

Replication-oriented study selection trace

Demonstration diagram for the replication package

Note. For the sake of replication and package size, the record-level demonstration in this replication package is centered on the **802 studies** retained after title/abstract screening, because these are the records for which step-by-step screening decisions are demonstrated in the CSV files. However, **802 is only the demonstration subset**. The **actual study flow in the paper** starts from **4,010 initial records** and ends with **107 final primary studies**. Both the full-study summary flow and the 802-record demonstration trace are preserved in this package.

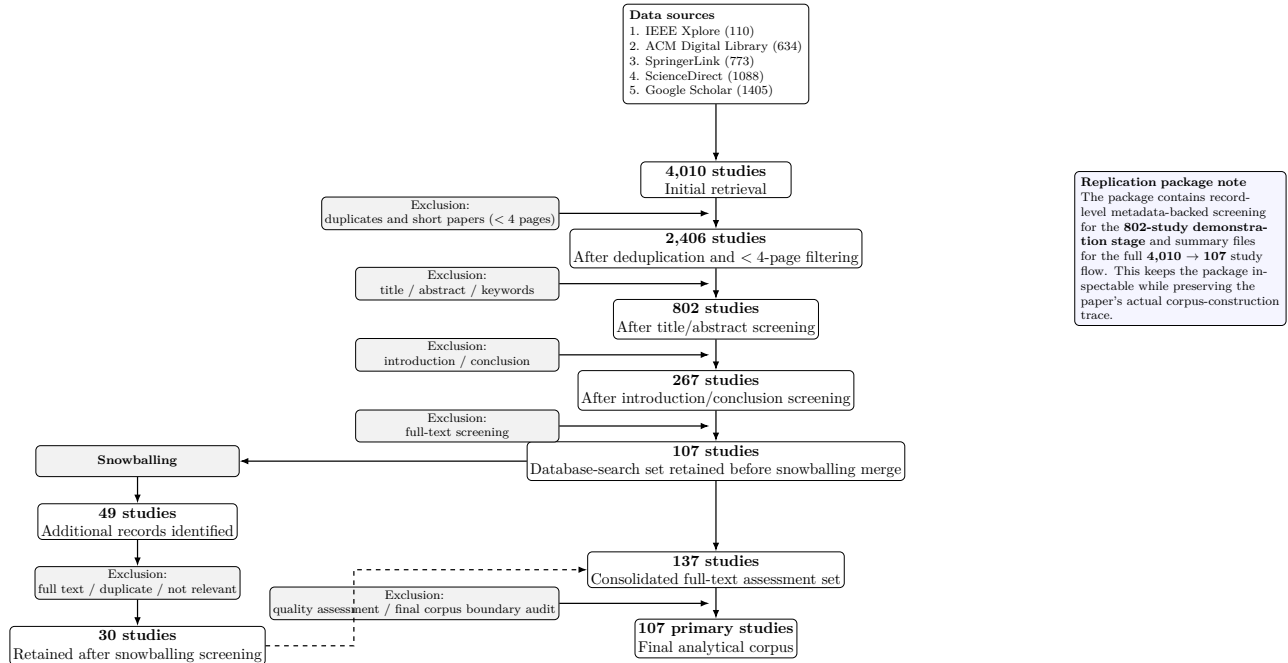

Figure 1: Study selection and screening process for identifying primary studies. The record-level demonstration included in the replication package is centered on the 802 records retained after title/abstract screening, whereas the actual manuscript flow starts from 4,010 records and ends with 107 final primary studies.
