

Study Selection Demonstration for Replication

Important note. For the sake of replication, this package demonstrates the screening trace most concretely with the **802-study title/abstract pool**, because this is the subset directly backed by the narrowed metadata and record-level screening decisions included in the package. This **802-study trace is only a demonstration subset**. The **actual study** reported in the manuscript began with **4,010 initial records** and ended with **107 final primary studies**.

Stage	Count	Meaning
Initial retrieval	4,010	Records retrieved from IEEE Xplore, ACM, SpringerLink, ScienceDirect, and Google Scholar
After deduplication and short-paper filtering	2,406	Duplicates and records under the page-length criterion removed
Title/abstract screening pool	802	Metadata-backed replication demonstration begins here
After introduction/conclusion screening	267	Narrowed to records sufficiently related to fairness requirements / AI systems
Database-screened set after full-text assessment	107	Retained from the database-screened branch before snowballing integration
Snowballing additions	30	Additional studies brought in through backward/forward snowballing
QA/integration pool	137	Combined set assessed before final corpus freeze
Final primary studies	107	Final analytical corpus used in the review

Figure 1: Study selection and screening process for identifying primary studies. For the sake of replication, the package demonstrates the metadata-backed **802-to-107** segment in an inspectable way. This is a **demonstration subset only**: the actual study began with **4,010 initial records** and concluded with **107 final primary studies**.
